

Design description:

This structure is a two-level automated planting station built primarily with treated wood for both the base and the upper deck, while the structural beams and support columns are intended to be fabricated using high-density 3D printing for precision and durability. On the lower level, two vertically oriented boxes serve as planting beds, each designed to hold soil and plants, and equipped with drainage holes at the bottom to allow excess water to filter through properly. A horizontally positioned box on the same level functions as the main water reservoir, collecting and storing the filtered water from the planters. On the upper level, a Rotoplas water tank is installed and connected to an automatic refill system, ensuring a continuous and regulated water supply that feeds directly to the plants below. The blue rectangular blocks visible on the structure serve as designated guide zones to delimit and organize the areas where the electronic components will be housed and mounted. It is worth noting that the routing of hoses and wiring, as well as the integration of key components such as solenoid valves, moisture sensors, flow regulators, and any additional control hardware, are still pending definition and will be incorporated in subsequent design iterations.
